## 16.317: Microprocessor Systems Design I

Summer 2013

Lecture 7: Solutions to Key Questions July 30, 2013

Assume an x86 processor is running in protected mode with the state given below (all values in hex); note that each memory location shown contains a descriptor about a particular segment:

 $\begin{array}{lll} \text{GDTR} = 00200000001\text{F} & \text{DS} = 0017 \\ \text{LDTR} = 000\text{B} & \text{SS} = 0018 \\ & \text{ESI} = 00001000 \\ & \text{EBX} = 0001120 \\ \end{array}$ 

| Memory          | Address  | Memory          | Address  |
|-----------------|----------|-----------------|----------|
| Base = 030010F0 | 00200000 | Base = 01000010 | 00200028 |
| Limit = 020F    |          | Limit = 1127    |          |
| Base = 00200020 | 00200008 | Base = 03170200 | 00200030 |
| Limit = 0017    |          | Limit = 03F7    |          |
| Base = 00200038 | 00200010 | Base = 1A000000 | 00200038 |
| Limit = 0010    |          | Limit = 01FF    |          |
| Base = 1200C000 | 00200018 | Base = 06B01000 | 00200040 |
| Limit = FFFF    |          | Limit = 0F07    |          |
| Base = 12340000 | 00200020 | Base = 05000120 | 00200048 |
| Limit = 00FF    |          | Limit = 000F    |          |

a. What is the base address and limit of the global descriptor table? How many descriptors does this table contain?

**Solution:** The base address and limit of the GDT are stored in the GDTR—the upper 4 bytes contain the base address (00200000H); the lower 2 bytes contain the limit (001FH).

To determine the number of descriptors, recall that:

- Each descriptor uses 8 bytes
- The size of the table, in bytes, is (limit + 1) = 001FH + 1 = 0020H = 32 bytes

Therefore, this table contains 32 / 8 = 4 descriptors

M. Geiger Lecture 7: Key Questions

b. What is the base address and limit of the current local descriptor table? How many descriptors does this table contain?

**Solution:** The base address and limit of the current LDT are stored in the LDT cache, which must be loaded from the appropriate descriptor in the GDT. The LDTR is a selector that points to the correct descriptor. Recall that, in a selector:

- The lowest 2 bits give the requested priority level
- The next bit (table indicator) indicates either global (0) or local (1) memory access
- The upper 13 bits index into the appropriate descriptor table to choose a descriptor.

 $LDTR = 000BH = 0000 0000 0000 1011_2$ 

- $\rightarrow$  Priority = 11<sub>2</sub>, table indicator = 0, index = 0000 0000 0000 1<sub>2</sub> = 1
- → GDT descriptor 1 (the second descriptor in the GDT) describes current LDT

Therefore, the *LDT base address* = 00200020H, its *limit* = 0017H, and the number of descriptors = (0017H+1) / 8 = 0018H / 8 = 24 / 8 = 3 descriptors.

c. What are the starting and ending addresses for the current data and stack segments?

**Solution:** In protected mode, the segment registers are selectors pointing either to the GDT or current LDT, as shown in (b). Therefore, the starting (base) and ending (base + limit) addresses for each segment can be determined after finding the right descriptor.

```
DS = 0017H = 0000\ 0000\ 0001\ 0111_2
```

- $\rightarrow$  Priority = 11<sub>2</sub>, table indicator = 1, index = 0000 0000 0001 0 = 2
- → Descriptor #2 (3<sup>rd</sup> descriptor) in LDT describes data segment
- $\rightarrow$  DS base address = 03170200H, ending address = 03170200 + 03F7 = 031705F7H

```
SS = 0018H = 0000\ 0000\ 0001\ 1000_2
```

- → Priority =  $00_2$ , table indicator = 0, index =  $0000\ 0000\ 0001\ 1 = 3$
- → Descriptor #3 (4<sup>th</sup> descriptor) in GDT describes stack segment
- $\rightarrow$  SS base address = 1200C000H, ending address = 1200C000 + FFFF = 1201BFFFH

M. Geiger

Lecture 7: Key Questions

d. What address is accessed by each of the following instructions?

Recall that protected mode addresses are calculated by adding the base address of the requested segment to the effective address calculated from the instruction. Part (c) of this problem helped you determine the starting address of each segment used.

i. MOV AX, [0100H]

**Solution:** Address = DS:0100H = 03170200H + 0100H = **03170300H** 

ii. ADD DX, [SI]

**Solution:** Address = DS:SI = DS:1000H = 03170200H + 1000H = **03171200H** 

iii. MOV AX, SS:[SI+EF00]

**Solution:** Address = SS:SI+EF00 = SS:1000H+EF00H

= 1200C000H + 1000H + EF00H = 1201BF00H

iv. SUB SS:[A200], CX

**Solution:** Address = SS:A200 = 1200C000H + A200H = **12016200H** 

v. MOV DX, [BX+SI]

**Solution:** Address = DS:BX+SI = DS:1120H+1000H

= 03170200H + 1120H + 1000H = 03172320H

vi. MOV CX, [BX+SI+1EH]

**Solution:** Address = DS:BX+SI+1EH = DS:1120H+1000H +1EH

= 03170200H + 1120H + 1000H + 1EH = 0317233EH
